

PLANNING GUIDE

Walkways and Driveways on Roofs and Decks

Life on Roofs

Important Standards and Guidelines

This planning guide is an English translation of the German original version. Therefore particularly German and European standards and directives are listed, as far as existent.

The walkway and driveway build-ups presented in the following have proven their reliability under the intended loads over many years. If specific standards and directives for the planning and the installation of walkways and driveways are valid in your country of course these are to be observed as well.

Guidelines for the Planning, Construction and Maintenance of Green Roofing –
Green Roofing Guideline (The Landscape Development and Landscaping Research Society e. V. (FLL))

Recommendations for the Planning and Construction of Traffic Areas on Buildings
(The Landscape Development and Landscaping Research Society e. V. (FLL))

Eurocode 1 (EN 1991) Actions on structures

- Part 1-1: Densities, self-weight, imposed loads for buildings (EN 1991-1-1)
- Part 2: Traffic loads on bridges (EN 1991-2)

Eurocode 2 (EN 1992) Design of concrete structures

- Part 1-1: General rules, and rules for buildings (EN 1992-1-1)

Waterproofing of buildings - German Standard DIN 18195

Regulations for Roofs with Waterproofing – Flat Roof Guideline
(Organization of German Roofer Society ZVDH)

A number of guidelines, technical bulletins and additional technical contract terms of
the german Road and Transportation Research Association (FGSV)

Not all standards and regulations are relevant for each project.

Please consider also all relevant local and national regulations.

The ZinCo Technical Department will assist you with project specific solutions.

General Information about Walkways on Roofs and Underground Garages

At a progressing rate, roofs are being used holistically and now almost everything which can be realised on ground, is possible on roofs as well.

To create long lasting and functioning walkways and driveways on roofs it is crucial to use the right technique. This planning guide will provide essential information.

Additionally to the self weight and imposed loads on walkways and driveways, horizontal forces and torsional movements may occur through acceleration, steering or breaking.

Types of loads, weights and frequencies of use are described in EN 1991-1-1 and EN 1991-2 (see table on the right).

Symbol	Force	Load	Additional Forces
	Category H Single person, maintenance and servicing on green roofs, e.g. roof gardener, chimney sweeper	total load 1.0 kN/m ² single load 1.5 kN (at a critical point)	
	Category A Residential Buildings	total load 4.0 kN/m ²	
	Category C Places of Assembly	total load 6.0 kN/m ²	
	Category F Light Vehicles up to 3t	total load 2.5 kN/m ² single load 20 kN	Horizontal forces from accelerating, breaking, steering
	Category G Lorries with 3t to 16t	total load 5.0 kN/m ² single load 90 kN	Horizontal forces from accelerating, breaking, steering
	Heavy goods vehicle with weights $\geq 16t$	total load 16.7 kN/m ² single load 170 kN (calculation according to EN 1991-2 possible as well)	Horizontal forces from accelerating, breaking, steering

EN 1991-1-1

Drainage

In contrast to the run-off delay or retention of stormwater that occurs on green roofs water must be discharged almost completely from walkway and driveway areas on and below the surface.

The water run-off coefficient for paved surfaces varies from $C = 0.8$ to 1.0 ; drains must be planned so that they allow for drainage on two levels: from the drainage level and from the surface area.

The ZinCo Product List offers the necessary system build-ups and accessories.

Materials

Materials for base layers are defined in contract terms of the FGSV (German Road and Transportation Research Association). The FGSV supplies information about bedding courses and jointing material within their directives, terms of delivery and technical bulletins. For a gravel base layer a grain size of $0/45$ is recommended. Grain size and grain size distribution ensure excellent compactability and stability. Bedding material can come in different grain sizes, but has to harmonize with the jointing material to prevent it from being washed out. Essentially, crushed stone

fines-sand mixtures have a grain size of $0/2$ or $0/4$ and crushed stone fines-chippings mixtures have a grain size of $0/5$. For water permeable surfaces grain sizes of $1/3$ or $2/5$ are recommended.

The ZinCo Technical Department is happy to help design the appropriate customised build-up.

Inclination

What inclination is essential on walkways and driveways? What fall is needed for a roof? What fall shall be used for the waterproofing and what fall for the surfacing?

The "Flat Roof Guideline" as well as the German Standard DIN 18195 require a minimum fall of 2% as standard; but also define how roofs with less than 2% can be constructed. On roofs with less than a 2% fall, the quality of waterproofing is even more important.

The inclination of the surface layer depends primarily on the surface material. A "stilted surface layer" does not need any slope since water can drain through the joints and standing water is not to be expected.

Surfaces made of concrete or asphalt require a minimum inclination of 1.5% and paver surfaces need a minimum of 2%. Establishing a slope is not a problem, if the waterproofing and the surface have the same slope. If a slope different from

the slope of the waterproofing has to be integrated into the surface, a gravel base layer is necessary. The slope cannot be created with the bedding layer, as it will result in uneven settlement. In general, when designing a fall the connection heights need to be taken into consideration. If possible, surfaces should not allow water to drain towards the building structure.

Therefore, these considerations should be incorporated early in the planning stage.

Walkways and Terraces on ZinCo Elefeet® – Pedestals

Some roofs do not have the load bearing capacity to carry the load of the base layer, bedding material and surface layer. In this instance the ZinCo Elefeet® are able to bear the load, and as a result of its minimal weight, only the weight of

the surface has to be taken into consideration. Surface water can be drained quickly and easily through the open joints and into the lower cavity; in addition, this open subspace provides good aeration. If higher Elefeet® are used, water pipes,

cables, or water hoses can be accommodated and used, for example, to irrigate adjacent intensive green areas.

Each Elefeet® is vertically adjustable by turning the swivel. Even after installation, a single slab can be lifted to adjust the relevant Elefeet®..

In this project it was decided to use Elefeet® to create a water reservoir underneath the surface layer in case of heavy rainfall.

Constructing surfaces on Elefeet® is not only restricted to small areas; this picture shows the outside area of a restaurant which is built on Elefeet®.

The installation of Elefeet® offers various important benefits:

- Precise levelling with vertical adjustment ring.
- Very low weight – only the surface layer needs to be considered.
- Elefeet Cantilever Arm Support to install edge areas.
- Open joints, free from pollution and weeds.
- Low maintenance and service required.

- Additional accessories for various applications.
- Proper drainage of paved surfaces and roofs.
- Useable on roofs without any slope due to large drainage cavity.
- Load bearing capacity up to 500 kg/pc.
- A dry surface reduces the chance of efflorescence.
- Wooden surfaces are easy to install and to be levelled out.
- Excellent aeration of concrete or wooden surfaces.
- Continuously vertically adjustable pedestals for build-up heights from ca. 20 to 460 mm.
- Hollow space useable for the installation of cables, hoses and other service elements.
- Very good mechanical and thermal protection of waterproofing and shielding of UV radiation.
- Simple, fast and weather independent application; no transport problems (e.g. gravel, mortar) to and within the installation area.

Precise in Detail – the System Programme Elefeet® and its Variants

Accessories:

Ordinary stilted pedestals are of less utility when it comes to solutions for corner and edge areas. Alternatively, the Elefeet® system offers a wide range of accessories for various applications:

The protection of waterproofing is ensured by the specially designed Elastosave mat (1).

The Cantilever Arm Support (2) allows for close connection to doors or insulating fillets.

The doorstep height can be reduced to a minimum of 50 mm, if a grill (3) is used in front.

Alternative sizes are available for grills and cantilever arm support. In addition, vertically adjustable elements (4) allow continuously adjusting up to 460 mm.

For non rectangular paving edges, the Mitre Cut Support (5) could be used.

The „quick“ alternative: Elastoring

If there is the requirement for a drainage profile while only a low build-up height exists, Elastoring is recommended.

The height varies between 5, 10, 15 and 20 mm. With the adjustment ring unevenness can be corrected; this can be done by cutting or folding the spacer and applied at individual support points.

There are special requirements of the substructure for the installation of the Elastoring: any slope showing up in the surface layer is caused by a sloped substructure and it is difficult to equalize;

therefore, the substructure must be levelled. Also, the substructure must have a sufficient load bearing capacity.

Elefeet® can be used for different surfaces such as the combination of concrete slabs and terrace grills.

Another variation is the application of a wooden surface. The desired slope can be created with the Elefeet® – Pedastals.

This surface rises from the threshold towards the perimeter to get sufficient space for a green roof application.

This example demonstrates the quantity calculation of Elefeet® or Elsastoring pieces:

Terrace area:	5.0 x 10.0 m
Concrete slab:	400 x 400 mm
Lengthwise:	$(10.00/0.40) + 1 = 25 + 1 = 26$
Crosswise:	$(5.00/0.40) + 1 = 12.5 + 1 = 14$

Number of ZinCo Elefeet®: $26 \times 14 = 364$ pieces

For pavers with 400 x 400 mm: 7.3 pieces/sqm required

For pavers with 500 x 500 mm: 4.6 pieces/sqm required

For pavers with 600 x 600 mm: 3.1 pieces/sqm required

The amount of pieces required is much lower on bigger areas due to less edge areas; whereas, smaller or geometrically unsteady areas need a much higher amount.

Basics for Walkways on Roofs and Underground Garages

Flat roofs – especially if they are sufficiently stable and easily accessible – are perfectly suitable for implementing walkways and sitting areas or even playgrounds and sports facilities.

The risk of falls from a height can be prevented by means of balustrades, guardrails or a combination of the two. When planning walkways on roofs the weight of the build-up has to be considered from the very beginning. For example the load bearing capacity of the roof and the

pressure resistance of the thermal insulation have to be sufficient for the weight of the walkway build-up.

During the installation of the different layers the waterproofing has to be protected from damage. So, first of all an appropriate protection layer must be installed. This can be a protection mat, but it is also possible to install a drainage layer which functions as a protection layer as well, such as Elastodrain® EL 202 or Protectodrain® PD 250.

For the installation and compaction of a gravel base layer it has to be considered, that built structures can be susceptible to vibration. The drainage of hard landscapes mostly takes place on the surface. Therefore a sufficient slope towards the roof drains has to be allowed for. Above the drains removable terrace grills ensure that the water gets downwards and also keep the drains accessible for maintenance.

During the construction phase flat roofs are often used as storage space or place of constructions machines such as on the roof of the Reichstag in Berlin.

The combined protection and drainage layer, which has been applied here still protects the waterproofing membrane under the large scale concrete slabs .

The base for creative surface designs: Protectodrain® PD 250 makes almost everything possible.

After the Filter Sheet TG is rolled out over the drainage layer, the bedding layer ist levelled to provide adequate stability to the overlaying slabs.

The Combination of Walkways and Green Roofs with Floradrain® FD 40-E

If the combination of walkways and green roofs is required, not only drainage and compressive strength are important, but also the water retention capacity.

Floradrain® FD 40-E as the core piece of the build-up meets all requirements of the roof and ensures durable functionality. Depending on the installation it allows for water retention (diffusion holes facing up) or drainage of water (diffusion holes facing down). Particular attention must be paid to the planning and construction of the transition between walkways and green landscape.

If Floradrain® FD 40-E is installed on the entire area on the protection mat,

edgings or foundations can be concreted directly on top of the Floradrain® FD 40-E without hindering the water to drain. Complex constructions with high installation or assembly costs do not apply since the incurred water flow can be drained, unhindered, along the underside of the drainage elements. Another benefit: There is only one kind of drainage element on the roof, which significantly reduces sources of error during installation.

At first sight a visitor would not realize he is on top of a roof.

Especially inner courtyards, which are visible from surrounding offices, offer the possibility to combine functionality and nature.

Green islands are visually pleasing and also bring life to roofs.

The possibility to include foundations in the build-up, allows the planner to design without limits.

The design of thresholds is flexible as long as they correspond to the "Flat Roof Principles" or any relevant national regulations.

This well proven solution with the Façade and Terrace Channel meets the guideline as a "special solution".

The drainage element used as formwork for a foundation ensures continuous drainage.

The continuous drainage layer allows for flexible designs and forms to be created in the subsequent layers.

Roof terrace shortly after completion:
green areas partly raised above and
partly levelled with walkways.

Walkways and other Paved Areas Drainage Elements: Build-up Alternatives and Details

Almost all ZinCo drainage elements are designed to ensure adequate compressive strength for pedestrian traffic. Various system build-ups can be used to design walkways on roofs for almost all

conditions. For various requirements, such as: an especially low build-up height (1); a higher water retention capacity of the build-up; e.g. for the combination of intensive vegetation and

dam up irrigation (2) or walkways on inverted roofs (3) ZinCo can offer an appropriate system build-up.

Drainage

Discharge of the surface water on sealed surfaces is just as important as safe drainage below the surface. ZinCo drainage channels allow the water to be drained off on two different layers, the surface layer and drainage layer. They also allow easy access for cleaning and maintenance.

In front of a facade, implementing a drainage channel is a good alternative to pebbles; it allows water to drain quickly, reduces water backsplash, and prevents plant growth. ZinCo grills and channels are vertically adjustable and can be used for diverse surface layers.

Edging and borders

A stable edging is almost as important as a durable drainage element. ZinCo stainless steel profiles and concrete kerbs both present visually pleasing detail solutions. Placing the elements on top of the drainage layer does not impair water drainage. Special constructions are possible. Challenge us!

Sporting surfaces

It is also possible to install special sport surfaces on ZinCo drainage elements (see example on page 30). The base layer and the drainage level underneath are able to drain the porous plastic surfaces. The ZinCo Technical Department is able to provide project specific solutions.

General Information about Driveways on Roofs:

Torsional Moments Are Added to Compressive Stress...

Loads

Driveways on roofs require both a load-bearing system build-up and a load-bearing roof construction.

If the static doesn't allow high loads, many trafficable roof surfaces are provided for load restriction, e.g. max. permissible axle load or trucks up to 3.5 tons.

Wheel loads have a narrow contact area, which leads to high point loads. It is crucial to plan sufficient load distribution either with load distributing surfaces or with an adequate base layer.

Load bearing concrete surface
→ load distribution across the entire slab

Bedding
→ additional load distribution of 60°

Bedding and paving
→ load distribution 60°

Concrete base layer
→ load distribution across the entire slab

Gravel base layer
→ load distribution 60°

Edging

The exceptional horizontal forces and torsional moments from steering, breaking and accelerating must be absorbed. Special arrangements in addition, such as slip sheets, are necessary to prevent the waterproofing from being damaged. The forces also have to be absorbed at the edging. Support of the edges from the back is required to keep the surface layer and the bedding material in place. If walls provide the edging of the paving it is important to ensure a mechanical protection of the waterproofing membrane, e.g. with stable metal profiles.

Pavement

Paver and slab sizes are determined according to the loads to be expected. Surfaces with low loads, for example walkways, have fewer requirements than surfaces with high loads. On driveways for cars and lorries additional forces such as torsional moments etc. occur, and the thickness of the concrete slabs has to be properly calculated. A greater slab depth results in a greater support surface and in a reduction of a possible distortion.

Thin pavers and concrete slabs result in larger compressive forces on the supporting medium below. With loose bedding material, these forces are absorbed vertically and result in deformation.

Thicker paver material absorbs the horizontal forces over a broader area eliminating the deformation in the bedding material below.

The arrows in the charts show the various forces. Thicker slabs absorb forces horizontally while thinner slabs absorb more vertically, due to a smaller supporting area at the sides. Therefore, deformation of the bedding layer will result with the thinner paver.

Installation pattern

The installation pattern primarily depends on the architect's or owner's requirements. But not every design will be able to carry the appearing loads. The interlocking installation of pavement reduces deformation of the surface and extends its longevity. Another alternative is the diagonal installation of the pavement which has a greater absorption surface for horizontal forces. (All 4 sides of a slab serve as load distribution.) Generally, big slabs placed with cross joints are not recommended for driveways, because of their low load distribution ability.

Driveways for Cars: System Build-ups with Stabilodrain® SD 30 or Fixodrive® FX 50

0°-slope

When building driveways on roofs of little or 0° inclination, puddles will form after rainfall and a special drainage layer is required.

Especially for installation under driveways the Stabilodrain® SD 30 drainage layer was developed. It is able to withstand heavy loads while maintaining efficient drainage in the 30 mm high cavity below.

With a drainage layer like Stabilodrain® SD 30 in place, conducting the excess facade water into the grills is no problem.

The edging, when concreted to the drainage element, provides a stable bordering.

If the entire roof surface is to be utilised, then an appropriate fall protection, such as a railing, is required.

Sloped roofs

If the support structure has a sufficient slope, the use of Fixodrive® FX 50 is an economic alternative. It will be delivered to the side with the pre-attached filter sheet and is therefore efficient to install. The connection by interlocking studs creates a large protection layer for the waterproofing.

Paving Slabs ≥ 100 mm

Bedding layer 30–50 mm

Gravel base layer ≥ 150 mm

Fixodrive® FX 50

Filter Sheet PV

Roof construction with suitable waterproofing

Driveways on inverted roofs

When working on inverted roofs, it is essential to avoid creating any sort of vapour barrier above it. With Stabilodrain® SD 30 this is possible. As a first layer, the Filter Sheet PV is installed on top of the XPS thermal insulation. The Filter Sheet PV is extremely stable and allows for air and vapour passage.

The 1 m x 2 m Stabilodrain® SD 30 elements are filled with chippings and covered with the Filter Sheet PV; this is to prevent small particles of the gravel base layer from being washed out. The surface of the gravel base layer runs parallel to the slope of the driveway surface. On top of this surface the pavement can be installed into a bedding layer.

System Build-up – at low Build-up Height with Elastodrain® EL 202

Vehicular traffic on a roof deck introduces very significant forces and stresses. As a result a very durable protection mat is crucial. The System Build-up for cars employs the extremely stable Elastodrain® EL 202 specifically designed for these applications. The large number of studs results in a very high compressive

strength. The studs distribute the load evenly on the substructure. This system is designed for heavy loads. A prerequisite is the early planning for the slope of the driveway surface. The desired slope should ideally be designed into the roof construction. It is not permissible to create the slope within the

bedding material for the pavers. If the roof slope is not the same for the waterproofing and the pavement surface then an additional gravel base layer is necessary for creating the desired surface slope. In addition, the pavement thickness and orientation need to be suited to the application.

The Elastodrain® EL 202 is placed over the Slip sheet TGF 20. To connect the single elements (1 m x 1 m) connectors are used. The waterproofing is protected right after the installation of the EL 202. The gravel base layer can be installed by carefully driving wheel loaders over the drainage layer.

The special Filter Sheet TG is used and carefully installed with an overlap of at least 200 mm. The bedding can then be applied in the appropriate height according to additional technical contract terms of the German Road and Transportation Research Association (FGSV) or relevant local regulations. It must also be ensured that the pavement is suitable for bearing the high traffic loads and that it is in accordance with the standards and regulations.

The joints of the pavement must be carried out according to German Standard DIN 18318 or any applying regulations. It is recommended that the jointing material is carefully flushed in to ensure the necessary support and stability. This surface layer will last the "lifetime" of the building as long as the condition of the joints is maintained regularly.

The Combination of Driveways and Vegetated Areas on Underground Garages with Protectodrain® PD 250

Due to easy accessibility and usually high load bearing capacity of underground garage decks it is often desired to work economically and apply the substrate with a wheel loader.

For this application the System Build-up "Underground Garage" with Protectodrain® PD 250 is perfectly suited as the protection and drainage mat Protectodrain® PD 250 protects the waterproofing against all kinds of mechanical stress already during construction. Covered with the very stable Filter Sheet PV it provides safe drainage for excess water.

Together with Zincolit® Plus and the System Substrates the System Build-up offers a lot of possibilities of landscaped design.

Protecteddrain® PD 250 is a stable, heavy-duty drainage board made of molded ABS plastic with a bottom side laminated-rubber protection mat and surrounding lateral step joints.

For a better fixing of the PD 250-boards special connectors are available. They can be plugged onto the "mushroom-shaped" studs along the edges of the abutting boards. We recommend one connector per meter.

Driveways for Lorries with Elastodrain® EL 202 and Base Layer

Occasionally, roofs and their surfaces have to bear exceptionally heavy loads in case of delivery or fire brigade access for example.

The size of pavers or concrete slabs has to be chosen to enable a horizontal absorption of forces and an economic installation pattern at the same time. A

load distributing base layer has to be designed in case of vehicles with more than 3 tons of total load. Especially heavy loads require especially good Protection Layers in order to safeguard the waterproofing. An additional Slip Sheet (2-layers) is also used to absorb torsional moments and forces from steering, breaking and acceleration to protect the

waterproofing. The edging surrounding the traffic surface is enormously important and must be stable enough to support traffic related forces. Protection of the waterproofing at the edge areas must also be taken into consideration. Elastodrain® allows heavy machinery to access the site even during the installation of the System Build-up.

Even heaviest equipment can be used for installation works when driving on top of the already build in base layer.

The base layer must be compacted before the pavers or asphalt are placed. The most suitable plate vibrator depends on the thickness of the base layer and the vibration susceptibility of the building.

For large areas a mechanical installation of the pavement or asphalt layer is possible.

Safe drainage

For "sealed" paving surfaces water drainage is required on two levels.

With the ZinCo Heavy Duty Inspection Chamber BES these drainage requirements are satisfied. It can be adjusted to nearly any height and is durable enough to be driven over by lorries.

The pre-assembled Filter Sheet flange of the inspection chamber prevents the bedding material and small particles of the base layer from being washed out and, therefore prevents settlement.

The Heavy Duty Inspection Chamber BES is equipped with a load distributing steel flange. Installed on top of EL 202, this inspection chamber is extremely stable.

Various drainage possibilities at a glance:

Drainage through joints of paving into the drainage layer.

Drainage over edging into the green area.

Drainage with solid driveable inspection chamber within the driving surface.

Drainage with walkable grill next to the driving surface.

Green Car Parks and Fire Lanes, Gravel Grass, Grass Pavers, Grid Elements ...

When surfaces are sealed they create especially high water run-off. Surfaces with a high level of use can not always be constructed water permeably. However, for drivable surfaces which are less frequented a green driveway can provide a solution. There is a wide range of

Gravel grass

solutions (see pictures below). The green portions range from little sections growing between pavings to full surface coverings of pre-cultivated grid elements. Even a lean system build-up without reinforcement is possible – see gravel grass below. This can be a favourable

Pavings

alternative as an ecological compensation layer with low visual demands. However, it is not recommended for frequently used areas.

Grass pavers

System Build-up with Grid Elements

Stabilizing Grid Elements can provide an attractive driveable surface when cultivated with grass. Depending on the use it needs to be mown 15–20 times per year. The water supply, in the absence of natural precipitation, needs to meet the local climatic conditions. It is recommended to install an automatic irrigation system.

The result is a visually appealing lawn. It is recommended to apply such Grid Elements only on less frequented parking areas. Any surfaces close to entrances should still be made of asphalt or concrete slabs. The use of pre-cultivated Grid Elements is also possible on natural soil.

The load bearing capacity of Grid Elements:

Car < 3 t max:*

5 crossings per day resp. max parking duration 8–10h

Lorries < 7.5 t max:

2 crossings per day resp. max parking duration 8–10h

Lorries < 7.5 t:

fire access and emergency access

* According to the grid producer

*) Composition:
70 % gravel 0/45
15 % quality top soil
15 % Zincohum®
Grain size distribution and water permeability
according to the applying standards and guide
lines.

Walk- and Driveways with Floradrain® FD 60 and Concrete / Details

System Build-up Floradrain® FD 60 with load distributing concrete layer

For the application on intensive flat green roofs without pitch, a combination of Floradrain® FD 60 and a load distributing concrete layer are optimal for creating small sized high load bearing driveways.

The wide drainage profile of Floradrain® FD 60 allows for higher drainage lengths beneath the surface layer. It is necessary to fill the Floradrain® board with concrete C25/30 (or higher grade) to a minimum height of 80 mm from the top of the FD 60. A reinforcement mat Q 257 A should be incorporated into the middle of the 80 mm base plate. Spacers hold the reinforcement mat in place.

To minimize cracking due the shrinkage, base plates require joints every 5 m lengthwise and crosswise. The joints need to be covered with a strip of filter sheet to avoid bedding material being washed into the joints.

Fire brigade accessible asphalt surface.

Asphalt
Reinforced concrete
Floradrain® FD 60
Protection Mat ISM 50
Roof construction with
root resistant waterproofing

Waterbound macadam

It is possible to build a waterbound macadam over Elastodrain®, Stabilodrain® and Floradrain®. The material can be installed when driving on top of the already built in base layer and needs to be compacted in layers. The upper layer is installed wet and then rolled; before it dries a chipping layer is added and compacted.

A continuous drainage layer based on Floradrain® FD 60 has been realized both below the planters and below the driveway.

On top of gravel base layers (see previous pages) resp. on top of a concrete base layer on Floradrain® FD 60 the installation of asphalt or other common landscaping

materials is generally possible.
Of course, a wide variety of materials can be combined.

For special situations please contact the ZinCo Technical Department.

Creative Solutions for Walkways and Driveways on Roofs

The Tivoli Congress Center and the Danish National Archives in Copenhagen

The roof landscapes of the two buildings extend to a total of 15.000 m². Whereas flower beds and lawn dominate the roof of the National Archives (on the right in the background), the roof of the Congress Center offers large-scale intensive planting (green roof) and playareas, enclosed by walkways of granite.

Gorch Fock School Hamburg

Part of the extension of the Gorch Fock School in Hamburg/ Blankenese, was the redesign of the existing sports complex.

Today an oval running track leads across the canopy roof of this ultra-modern building, coming from the natural ground and running above eight class and group rooms. It then leads back to the natural ground in the direction of the sports field.

To realize this running track on a roof area, a System Build-up with the extremely

resilient Elastodrain® EL 202-sheet, made of solid vulcanized rubber, was used. EL 202 was applied on top of a separation and slip sheet and fixed with connectors to a 400 m² protective and draining surface. A heat-resistant filter sheet was laid on this layer before the porous asphalt was distributed. The final step was the application of the tartan coating.

Subaru Building Singapur

In order to make the purchase of their model attractive to potential customers, the Subaru hub office has located its showroom on top of their roof.

The visual center piece on the show roof is the drive-through tunnel. The Elastodrain® EL 202 guarantees the stability stand of the construction, and it drains large quantities of water which appear in short-term. Already during installation EL 202 is very useful. Due to its pressure stability and its protective function it allows for comprehensive operations on the roof.

The test track offers a wide variety of challenges, such as a sand dune, steep approaches and descents, sharp curves, hollows and bumps, inclined planes and many different surfaces. Horizontal

forces develop from driving, especially from steering, breaking and accelerating. Two layers of Separation Sheet TGF 20 below EL 202 prevent these horizontal forces from damaging the water proofing.

Repsol Tower Buenos Aires

At the foot of a 160 m high office tower, this 4500 m² underground garage offers a natural space to unwind in the middle of the big city. Besides trees and lawn generous walkway and glass gravel surfaces were created as well.

Long-Lasting and Technically Sound Solutions

This Planning Guide aims to give you a general overview of the technology walkways and driveways.

Our technical experts will be pleased to advise you on specific solutions for your own individual building projects: from the planning phase right through to creating your specification texts.
